COMPUTER NETWORK

What is a Computer Network?
A computer network is a group of two or more computers connected to each other by a *cable*, *telephone lines* or through *wireless communication.* When computers are connected to a network, they can share resources on the network, such as documents, programs, printers, modems, etc.

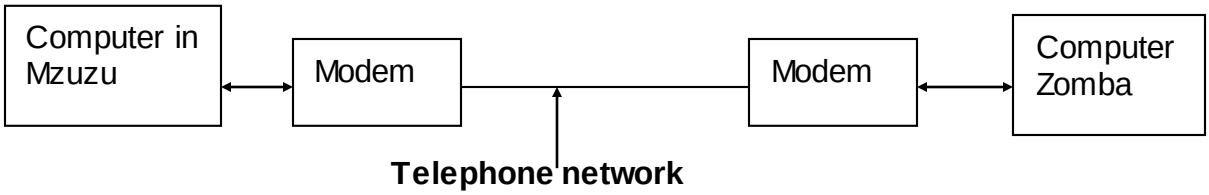

A number of computers can be connected to share a single hard disk using a network. Such a hard disk is referred to as a **File Server**.

There are two main types of network configurations: Local Area Network (LAN) and Wide Area Network (WAN).

Local Area Network (LAN)
This is an interconnection of computers, terminals, and other devices at a single geographical site, for example, within the same adjacent buildings.

Wide Area Network
This type of Network involves connection of computers in different locations either national or international. It is designed to cover a wider area than a local area network. This is achieved by use of telecommunication equipment, for example, modems, telephone lines, satellite or wireless communication.

For a computer to communicate with another computer over the telephone network, a MODEM (short for **Mo**dulator **Dem**odulator) is needed. This piece of equipment changes data from digital (machine code) to analog form so that it can be carried over the telephone lines. At the receiving end another modem changes that data from analogue back to digital form for the computer to read and understand.

WHAT IS THE INTERNET?

The Internet is a network made up of hundred of thousand of computers all over the world, with millions of users connected electronically by communication lines (telephone lines, fibre-optic cables and other links). These computers can share and exchange information. The Internet is a network of networks.

The Internet is the hardware – the computers and the connections between them – and the software that let them communicate with each other. It is the base on which the Web is built.

What can you do with the Internet?
Applications on the Internet can be divided into five main areas.

1. **Information Browsing** – The World Wide Web (WWW) is powerful tool for searching for any type of information from any database on the Internet. You can use it to have access to some famous libraries in the world.
2. **File Transfer** – There are tools available on the Internet that will enable you to transfer files of interest from a remote computer to your computer, provided you have access rights.
3. **Use of other computers** – Some facilities on the Internet will allow you to log into a remote computer and use it just as if you were a terminal connected directly to that computer.
4. You can join international debates or discussion groups (called Usenet groups) that discuss a wide range of topics.
5. Electronic mail.

When you have access to the Internet you can:

- Send mail to friends
  → Messages are delivered almost immediately
- Share ideas with others
  → In real-time chat rooms
  → Through articles in newsgroups
- Pursue a special interest
  → Exchange ideas, advice and files
- Download files
  → Text, graphics, programs

- Look up information in reference “books”
  → The World Wide Web Virtual Library
  → CIA World Factbooks
- Search or browse through the Web
- Watch video clips
  → Look through cameras thousand of miles away
- Get the latest national and international news
  → Weather reports, stock market prices, travel information
- Go shopping
  → Books, CDs, gifts, PCs

What do you need to know?
Browsing the Web and sending and receiving email are the two main uses of the Internet for the vast majority of people.

You should at least be able to:
- Start programs;
- Run commands from menus and from toolbar buttons;
- Set options and make choices in dialog boxes;
- Use a mouse to select objects and start operations;
- Save and open files, and find your way around your folders;
- Move and resize windows.

How do you get into the Internet?
People get access to the Internet in one of two ways:
- Local Area Network (LAN)
- Internet Service Provider (ISP)

To link to the Internet using an ISP, you must be able to set up a terminal at home. For this you will need:
- A computer
- A modem – to link to the computer to telephone lines
- Dial Up Networking software – to manage the connection between your computer and the rest of the Internet.
- Web browser to enable you to:
  → Surf the Net
  → Send email

WHAT IS THE WEB?

The Web is the part or service of the Internet that uses text, images, sound, and video. It links documents together so that just by using the computer mouse you can jump from document to document, even if the documents are on computers in different locations or different countries. This linking is sometimes called

hypertext. Currently, there are hundreds of thousands of websites, with tens of millions of pages of information.

The **World Wide Web** is a collection of electronic documents that are linked together like a spider web. These documents are stored on computers called **servers** located around the world. To access the World Wide Web, you need a web browser – a program that can display the text and images that make up Web pages and interpret the links that will take you from one page to another.

The Web has evolved into a global **electronic publishing medium** and increasingly, a medium for conducting **electronic commerce**.

What information can I find on the Web?
You can find something about just any subject on the Web. The Web has great resources for job hunting, ravel, news, entertainment, law, government, statistics, cooking, computers, health – you name it.

All kinds of people and organizations put up information on the Web: government agencies, private companies, universities, non-profit and social service organizations, small businesses, individuals of all kinds.

Things to be aware of in order to use this tool effectively

1. Anyone can publish on the Web. You should not belief everything you read. Not everything on the Web is accurate or authoritative. Evaluate the source of the information you find.
2. They are things on the Web that you may find offensive.
3. Even though the Web is huge and growing all the time, not everything can be found there. You should still use all other great resources at the library, like books, magazines and CD-ROMs.

Why are the Internet and the World Wide Web important for education?
The Internet and the World Wide Web are important to a field like education for many reasons. The most significant reason is that the Internet brings a massive set of information resources into the classroom that has never been available before. Students can easily visit web sites around the world. Students with connection to the Internet and the World Wide Web can have access to the great museums and libraries of the world. Not only can you wander through the great museums of the world via the Internet, but you can also exchange scientific research data with students across the world and even talk to scientists by e-mail in remote locations of the world.

What Is the Web Made of?

The Web consists of:

- Your **personal computer**
- **Web browser software** to access the Web
- A connection to an **Internet service provider** (ISP)
- **Servers** to host the data
- **Routers** and **switches** to direct the flow of data

What is a Web Browser?

To access the World Wide Web, you need a web browser – a program that can display the text and images that make up Web pages and interpret the links that will take you from one page to another. A Web browser is a type of software that provides users with a graphical interface for connecting to and navigating through the World Wide Web. This software program is used to access the World Wide Web. It retrieves data from remote web servers and displays a web page.

Internet Explorer and *Navigator* are the two most popular browser programs currently in use. These two browsers work approximately the same way. Some terminology is different. Both are being constantly upgraded to make them more competitive with one another.

STARTING MICROSOFT INTERNET EXPLORER

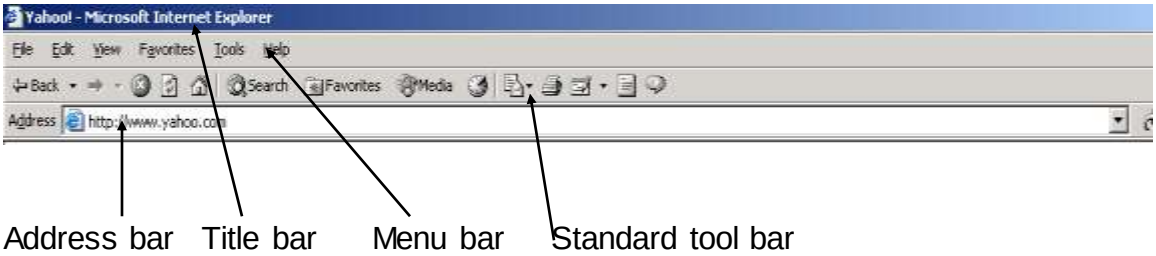

To start Microsoft Explorer:

- Choose the Internet Explore command from the Start menu – this command is usually stored in either the **Start Programs** submenu or the **Start Programs Internet Explorer** submenu.

  Or

- Double-click on the Internet Explorer icon on the desktop.

Anatomy of Microsoft Internet Explorer

- The **title bar** is the bar at the top of a window. It shows the name of the application program or document in that window.
- The **menu bar** is directly below the title bar. It contains a list of menu titles. To display a particular menu, click on the menu title, or press **[Alt]** and the space bar.
- To access commands on menus, click on the name of the command in the pull-down menu or press the underlined letter in the name of the command.
- The **Standard toolbar** is a group of buttons that usually appears directly below the menu bar. You can click on the buttons to gain fast access to frequently used operations. You can only use the buttons on the toolbar if you are using Microsoft Internet Explorer with a mouse.
- The **Address bar** displays the Web address (URL) of the page you are currently viewing, or the location of the currently open file. You can use it to enter the address or location of a page of file you want to open.
- The **Internet Explorer icon** shows when a Web page or other file is being loaded into the browser window. As the page or file loads, the icon is animated.
- **Scroll bars** including **scroll boxes** and **scroll arrows** sometimes appear at the right and bottom of the browser window. They are used to scroll different parts of the window into view.
- The **Status bar** is a line at the very bottom of the Microsoft Internet Explorer window. It displays the address or location of the page o file being opened, along with progress information.

Working with the Status Bar

The **Status bar** is a line at the very bottom of the Microsoft Internet Explorer window:

- If a menu command is highlighted, the status bar displays a message describing the function of that command.
- If the mouse pointer is positioned over a **hyperlink** on a page, the status bar displays the full address of the page that will be opened when you click on the hyperlink.
- While a page is downloading from the Internet, a progress bar appears in the middle of the status bar. Information about how many items there are left to download on the page may also appear on the right of the status bar.

Working with Text Boxes

Entering information in Text Boxes:

- To change information in a text box, activate the text box by clicking in the text box, then type the new information.
- When you point to a text box, the pointer changes to a text pointer. If you click in the text box with the text pointer, a flashing vertical line appears – this indicates the insertion point.
- If the text box contains the insertion point, what you type appears at the insertion point.
- If the text box contains highlighted text, what you type replaces the highlighted text.
- If the information in the text box is not highlighted (if you only see the insertion point), you must use **[Delete]** or **[Backspace]** to remove the old information.

Setting up Internet Explorer (IE)

To set up a few options after IE has done the routine setup, open **Internet Options** through the **Tools** menu.

The General tab

Some of the key options are on the General tab. Internet Explorer will try to connect to the **home page** at the start of each surfing session. If you always want to start at the same place, enter its URL in the Address text box, or come back to the Internet Options and click **Use Current** when you are next on that page. If you want to choose a new page each time, select **Use Blank.**

Internet Explorer caches (stores on disk) the files for pages as you visit them. If you revisit the page, and the files are still the same, they are loaded immediately from your disk, so that you do not have to wait for them to download again. The **Delete Files...** and **Clear History** buttons will both free up space on your hard drive, if needed.

Click **Settings** to change the amount of space allocated to the cache. If you are going to do a lot of surfing, and will return to the same places regularly, allocate more space.

Set the **History** limit to fix how many days to keep track of the places you have been to. Click **Clear History** if you want to wipe your tracks.

What is a Web Page?

A **web page** is an electronic document written in a computer language called **HTML** (Hypertext Markup Language). **Web pages** are stored on **web servers** located around the globe. They can contain text, graphics, video, animation, links to other pages, links to other files, and sound, as well as **interactive features**, such as data entry forms.

Note: The amount of information on each page can vary considerably. If there is more information than can be displayed in the browser window, you can use the scroll bars at the bottom and/or right of the window to view the rest of the page.

Uniform Resource Locators (URLs)

With so many millions of Web pages, files, and email addresses that can be reached over the Internet, a standardized and systematic way of identifying them is essential. Uniform Resource Locators provide this. When you type correctly a URL of a Web page, the browser will go to the right site and locate the item.

URLs are the method by which all resources on the Web are addressed. Web resources are usually (but not necessarily) computer files, such as Web page documents. The URL specifies exactly where a resource can be found. All resources have unique URLs. The URL contains the following information:

- The type of service that should be used to get the resource.
- The name and address of the host computer storing the resource – this sometimes includes a country code.
- The port number used by the service we want on the host computer (usually omitted).
- The location (i.e. the directory path) and name of the resource.

This information is presented in the following way:

Type_of_service://host_name_and_address:port_number/directory_path/resource_name

Example:

Consider the following URL:
http://www.soc.staffs.ac.uk/news/news.html

- The above URL begins with the letters **http.** This tells us that we need to use the Hypertext Transfer Protocol (HTTP) to access this resource. Hypertext Markup Language (HTML) documents are usually accessed using this protocol, and HTML is a language in which Web pages are created.
- A colon and two forward slashes **(://)** separate the type of service used to retrieve the resource from the rest of the URL.

- The name and address of the host computer is **www.soc.staffs.ac.uk,** where **www** is the name of a World Wide Web server at **soc** (the School of Computing) at **staffs** (Stafford University), which is an **ac**ademic site in the **uk**. This part of the URL is called the **domain name.**
- The port umber has been omitted, so a default port number will be assumed. The default port number for an HTTP server is **80**, but this is rarely required.
- The next forward slash separates the domain name and port number (if included) from the resource name.
- The resource name may include a directory path specifying its exact location on the host computer. In the above URL, the resource is a Web document **news.html**, which is stored in thee **news** directory. Hence the full path is **news/news.html**

Note:

- The last part of the domain name describes the type of domain. The convention is to have **.ac** or **.edu** for academic or education, **.co** or **.com** for commercial, **.org** for non-profit organizations, and so on. Others include **.net** for network providers, and **.gov** for government bodies..
- There are around 250 country codes that can be included in a domain name (such as **.uk** for United Kingdom, **.mw** for Malawi, **.za** for South Africa). As the Internet originated in the U.S.A., the county code for the U.S.A. (**.us**) is rarely used.
- The Web page document addressed in the above URL has the extension **.html**. Most Web pages created using HTML end with either **.htm** or **.html**.

Using URLs

A URL indicates where the web page is stored on the Internet.

Tip: URLs almost never use back slashes (\). All slashes are forward slashes (/).

- You need to type a URL exactly for your browser to locate the desired web page.
- Although URLs may contain spaces between characters, they usually do not.
- The location box or address field on your browser indicates the URL of the page you arrived at after clicking a link.

> If you know the URL of a Web page you can type it directly into Microsoft Internet Explorer and go straight to that page. This can save a lot of time in comparison to following links to that page. Where the URL is for the top page of a site, it will end with a slash (/). This can be omitted.

To enter a URL directly:

- Click in the **Address** bar to position the insertion pint in it – if there is any text in the **Address** bar, it will be selected:

- Start to type the new URL – what you type will replace the selected text.
- As you type the new URL, Microsoft Internet Explorer checks to see if what you have typed so far matches any other URLs you have typed. If it does, the match is automatically entered in the **Address** bar - the suggested part of the URL is highlighted.
- When you have finished typing the URL or when the correct URL has been suggested, press **[Enter]**.

Note:
You do not need to type **http://** at the start of any URL you enter. Microsoft Internet Explorer will add this for you. Thus the URL:

http://www.mzuni.ac.mw/

can be entered as:

www.mzuni.ac.mw

- Remember, while the resource is being opened, the Internet Explorer icon is animated and progress information is displayed in the status bar.

Introducing Home Pages

The first page is called the home page, which acts like an index, indicating the content on the site. From the home page, you can click hyperlinks to access other web pages.

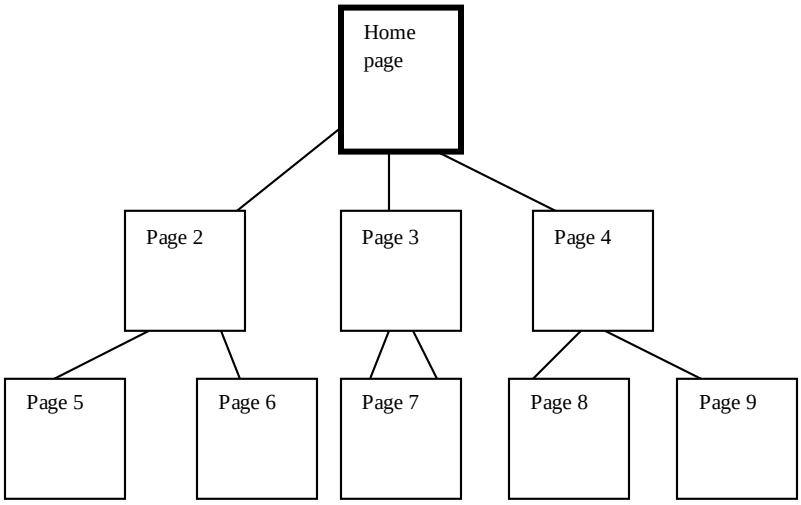

In general, a home page is the **default** Web page that is opened when you visit a Web site without specifying the name (or path) of the page you want to view. For example, if you enter the URL http://www.microsoft.com in the address bar, the Microsoft home page will be displayed.

Before you can use a URL, you have to know it. There are several sources:

- As you browse the Web, you may find a hyperlink to a page you want. Point to it to display its URL in the status bar, and make a note of it.
- If you join any newsgroup, you will often see postings about relevant pages on the newsgroup area of interest, particularly new ones.
- Internet magazines and newspaper columns often have 'What's New' features.

Websites

A **website** is one or more web pages that relate to a common theme, such as a person, business, organization, or a subject, such as sports.

Navigating the Web

There are three main ways to move between web pages or websites:

- Clicking a **text hyperlink**.
- Clicking a **hyperlinked graphic image**, such as a button, photograph, or drawing.
- Typing the **URL of a web page** in the **location box** (also known as the address field) of your web browser and the pressing the **Enter** or **Return** key.

Moving from page to page on the Web is sometimes referred to as “surfing” or “browsing” the Web.

Hyperlinks

Most Web pages contain hypertext links **(hyperlinks)** which usually connect you to one of the following:

A different part of the same page – useful if the page contains more information than can be displayed in the browser window.

A different page, either at the same site or somewhere else on the Web.

A file that you can open or download to your computer.

Almost anything on the Web can act as a hyperlink. However, the majority of hyperlinks take one of the following forms:

Coloured and/or underlined text (the default colour for a hyperlink is usually blue).

A button image, which may contain text or graphics

A picture (for example, a company logo).

When you position the mouse pointer over a hyperlink, the pointer changes to a hand: . A URL appears in the **status bar** at the lower left of your web browser.

Microsoft Explorer keeps a record of the pages you have viewed. If you return to a page that contains a link to a page you have recently viewed, you may find the hyperlink is displayed in a different colour. Internet Explorer does this to remind you that you have already **visited** the page identified by this link.

Note:
The resource (Web page, downloadable file, etc) to which a hyperlink points can be local (on the same machine as the current page) or on another computer anywhere in the world.

Navigation Buttons on the Toolbar

Microsoft Internet Explorer keeps a record of the Web pages you visit.

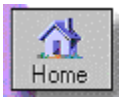

The Back 

and Forward 

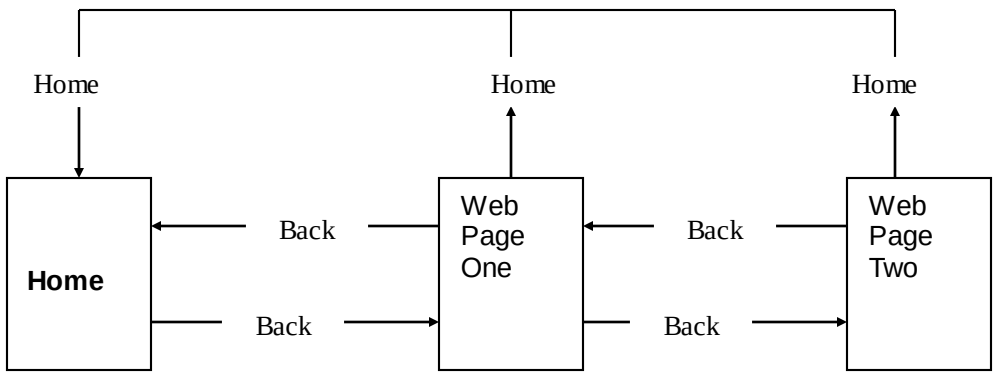

buttons enable you to navigate around the pages you have visited during the current session:

Example:

Consider the following example where you two Web pages (other than your default home page) in a session, i.e. without closing Microsoft Internet Explorer.

You can use the Back, Forward and Home 

buttons to navigate between these pages as shown in the following diagram:

Note:

- You can click the down arrow next to the Back and Forward buttons to display a list of pages you have just visited. You can click any page in the list to open that page. (A maximum of nine pages can be displayed in the list.)
- When you close Microsoft Internet Explorer, the navigation information in the Back and Forward buttons is reset. You cannot use these buttons to navigate around pages visited in previous sessions.

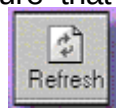

Some Web sites contain complex graphics, sound or video which, if you are trying to access them when the Internet is busy, can take several minutes to download.

- If you change your mind about opening a Web page or if the Web page is taking too long to download, you can use the stop 

button to halt the downloading process.
- When you click on the Stop button, Microsoft Internet Explorer attempts to display what it has downloaded up to that point. You can then read any information and click on any hyperlinks that are available.

Note: Usually, Microsoft Internet Explorer stores all the Web pages you have visited recently (including elements such as graphics) in the **Temporary Internet Files** folder on your PC's hard drive. This folder is known as a **cache.**

- If you have already visited a page during the current session (or during another recent session), some or all of the files associated with that page may still be stored in your **Temporary Internet Files** folder. Microsoft Internet Explorer can make use of these stored files so that the page can be opened more quickly.
- However, the contents of Web pages can often change. Microsoft Internet Explorer usually checks to see if the page available to download is newer than the stored page. If it is, the new page will be downloaded.

You can force Microsoft Internet Explorer to download the page again, and so make sure that any information, hyperlinks, etc. are updated by clicking on the Refresh 

button.

Printing Pages

Microsoft Internet Explorer enables you to print the currently displayed Web pages, including any graphics displayed on the page. If the page contains more

information than can be printed on a single sheet, Microsoft Internet Explorer automatically paginates the page before printing.

To print the current page:

- Choose **File** then **Print** command.
- When the Print dialog box appears, make sure the correct printer is selected in the **Printer Name** drop-down list.

Note: You can also print the currently displayed page by clicking on the Print  button in the Standard toolbar – the Print dialog box is not displayed.

Saving an Image from the Web

- Move your **cursor** over the graphic.
  Click the **right mouse button**. A pop-up box appears.
- Save the image to your hard drive by selecting a **Save** option.

You can accept the current file name or rename the file. (Graphic files are usually in **.gif** or **.jpg** format.)

Finding information

Finding information that interests you on the Web is not usually difficult. To find information you may use directories, search engines and portals.

Directories – They have organized links to large parts of the Web – and to much of the rest of the Internet. A number of organizations maintain directories. Some of these are focused on specific topics; others offer a systematic overview of the Web's resources. Yahoo is probably the best known of these, and is an excellent place at which to start researching a subject.

Using Yahoo: Yahoo is one of the best of the general directories and by far the most popular. Yahoo classifies all the Web pages in its database into a hierarchy of categories. You can search for all Web pages in the Yahoo database by entering key words or by selecting the appropriate categories.

To access Yahoo, navigate to the following URL:

http://www.yahoo.com

The following page will open:

Searching Yahoo for key words or phrases:

- If you want to search the Web pages containing a particular word or phrase, type your search terms in the text box on the form, then click on the **Search** button.
- The results of your search are presented in a new Web page. The Search Result page contains links to the categories which match your search terms, the web sites that match your search terms and the categories to which those web sites belong.
- You can view any of the categories or Web sites found by clicking on the link. At the bottom of the Search Result page you can click on a link to obtain the next batch of matches found.

Searching Yahoo by Category:

- If you do not want to search for key words or phrases, you can search through a hierarchy of categories to find web pages you are interest in.
- In the main body of the Yahoo home page, click on the general category in which you are interested.
- Yahoo displays a new Web page containing a list of subcategories of the category that you selected. Click on the subcategory to narrow down your search.
- Yahoo may display more new Web pages containing further subcategories of the category you selected. As each page of subcategories is displayed, click on a subcategory to narrow down your search further.
- Eventually Yahoo displays a list of Web pages in the subcategory in which you are interested.
- You can view any of the pages found by clicking on the link. At the bottom of the list you can click on a link to obtain the next batch of pages found.

Note:

- The Yahoo home page also offers links to several other services provided by Yahoo.
- For example, the **News** section of the page contains links to up-to-date news stories and the **Marketplace** section contains links to economic services.
- Yahoo also offers several specialist search forms, which enable you to search by key words or phrases for particular kinds of web documents, people or services. To access one of these search forms, click on one of the links in the upper section of the Yahoo home page.

Search engines – You can use search engines to hunt for pages that contain given words**.** They are most useful when you are looking for information on a very specific topic as they can pick.

Overview of searching

The Web is growing rapidly and hundreds of thousands of pages of information are being added every day. It is also developing in an extraordinarily ad hoc and erratic way. Hence finding what you are looking for can be extremely difficult. The Web is a very large and complex place. Information is duplicated and distributed amongst many thousands of different servers across the world. The main problem with finding information, software or anything else on the Internet is:

- There is a huge amount of information on everything
- There is no central place that holds an index of everything on the web.

However, there are various indexes to some of the available information. These indexes, called **search engines**, provide a convenient and easy way to finding some (but by no means all) Web resources especially if you are researching an esoteric topic. At these sites you can search their databases that hold key information about pages and sites on the Web.

How Search Engines Work

Search engines are programs called **software agents** that automatically traverse the Web, retrieving and indexing Web pages. Starting with the sites they know, they seek out all the links embedded in those pages, follow them, and then repeat the process for all the new sites they come across. Indexing software then compiles enormous databases of information, addresses and links. These databases are accessed when someone submits an enquiry.

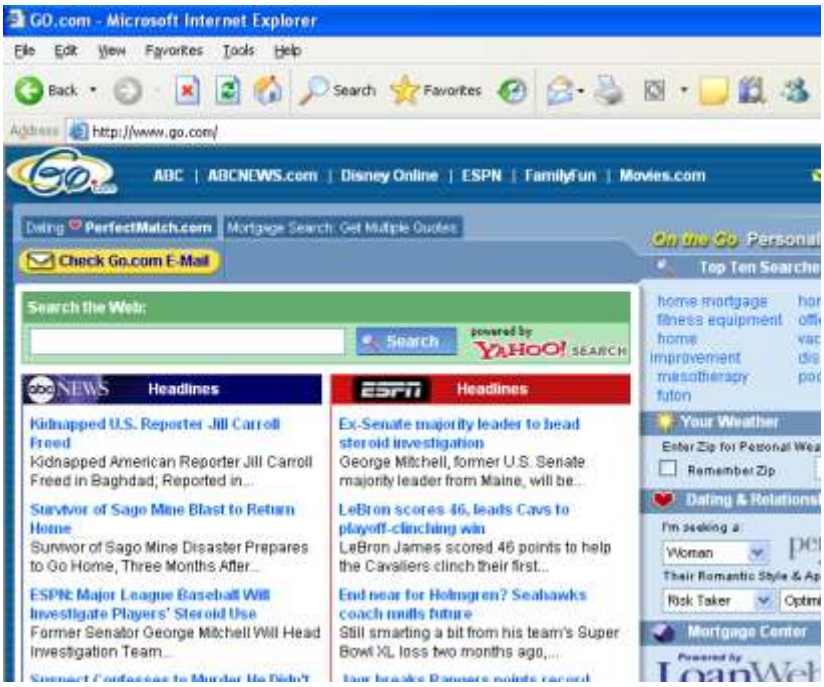

Search engines vary in the way they collect and hold data, and in their degree of completeness. 100% coverage is impossible as pages are being added and

changed constantly. If you do not find what you want using one search engine, it often worth trying another.

Some popular search engines include Go.com, WebCrawler, AltaVista, and Google.

Go.com

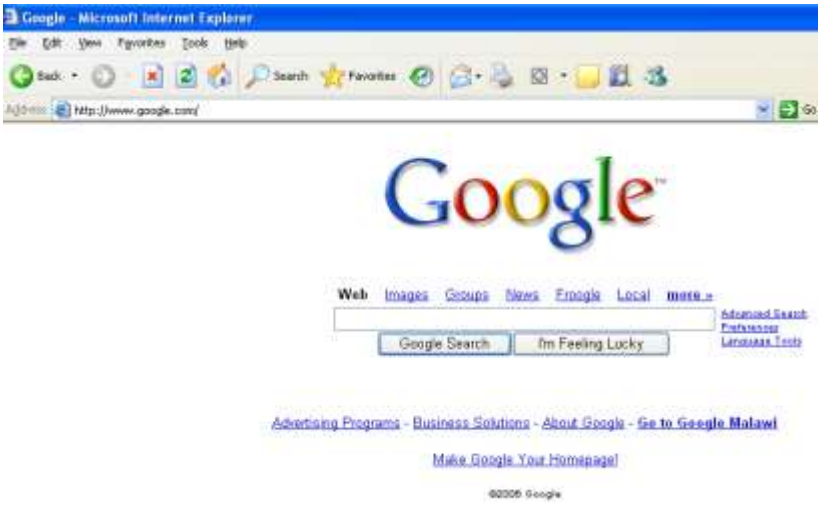

Go.com is one of the most comprehensive search sites. Its database contains millions of pages. The biggest problem at any search site is in defining your search with sufficient accuracy that you do not get too many results. Fewer relevant links are far more useful than a mixed bag of many links that will take hours to sort through. The URL for Go.com is http://www.Go.com

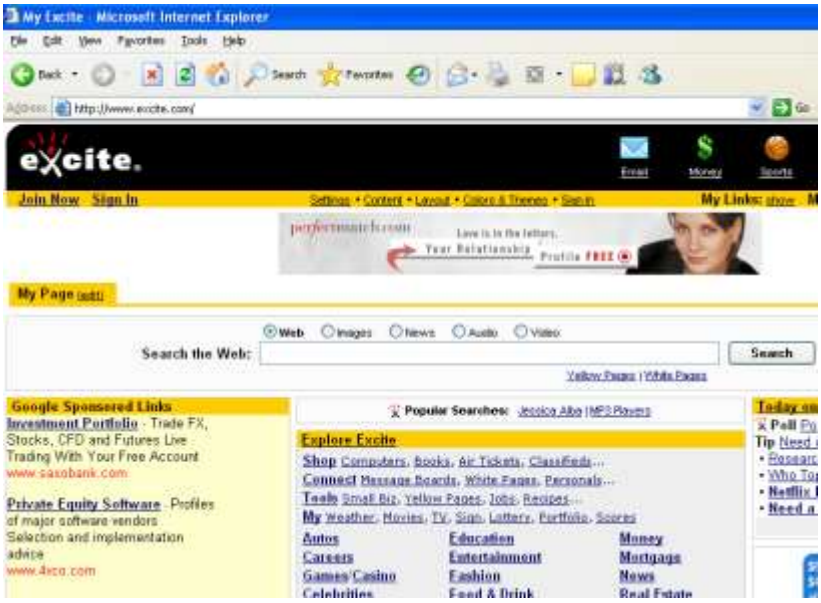

The WebCrawler

The WebCrawler gets its information from a 'spider' which constantly travels the Web, looking for new pages. Although its database is huge, it returns results fast. Its real problem is to define the search closely so that you do not get too many matches.

Portal sites – These act as gateways through which people will pass on their way into the Web – will lead you to selected material on a wide range of popular topics, as well as providing news and other services. Portal sites provide their visitors with a whole range of services including a guide to Web sites, email, chat rooms, personalized news, weather, sports and market reports. Most of the portals are based around directories or search engines

Excite, one of the leading portals.

Search Syntax

Capitalizing Names and Titles

- If you capitalize adjacent names, some search engines treat the words as a single name or title. For example:

  Rock Hudson

- If you do not capitalize a name or title, it may be treated like any other group of words, and you will find sites about rock climbing, rock music and the Hudson River along with sites about the movies actor.
- If you search for lower case words, most search engines will find Web pages containing capitalized words also. For example, **paris** will find matches for **paris, Paris,** and **PARIS.**
- If you include some capital letters in your search terms, most search engines will only find results that match the case of the search terms exactly. For example, submitting a query for **parIS** will search only for matches of **parIS.**

Using commas (,) to separate Names and Titles

- If you want to search for several names or titles, use commas to separate them. So, to find sites that mention **Bozo** and **Ronald MacDonald,** you would search for:

  Bozo, Ronald MacDonald

- If you do not use a comma between names, they will be treated as one long single name. A search for **Bonzo MacDonald** will not find any sites on clowns.

Using Double Quotation marks (“) or Hyphens (-) to indicate Phrases

- Use double quotation marks (“) around words and phrases that must appear next to each other. For example:

  “stupid pet tricks”

- The example above will find sites with those words adjacent to each other. If you do not use quotes, the search engine would find sires that include the word **stupid,** the word **pet,** the word **tricks,** or any combination of the three.

- Alternatively, some search engines enable you to use hyphens between words that must appear together. For example:

  stupid-pet-tricks

- When using hyphens, make sure you leave no spaces between the words.

Using a plus sign (+) in front of a word that must appear

- If you are searching for several words, most search engines return all the Web pages that contain all or some of the words you specify. To indicate that a word must appear in all of the search results, type a plus sign (+) before the word. For example:

  city guides +London

- Do not leave a space between the plus sign and the word that must appear.

Using a minus sign (-) in front of a word that must not appear

- To exclude a word from your search, type a minus sign (-) before the word. For example:

  Python –Monty

- The example above will find you sites on snakes and programming language, but not the British comedy group.

- Do not leave a space between the minus sign and the word you wish to exclude.

- To narrow your search results by searching for one word, and then searching for another word within that set of results, type a Pipe (|) between the first word and the second:

  dogs | Dalmatians

Using an Asterisk (*) to search for partial matches

Example: quilt*

- This query matches sites that contain at least one word such as **quilt, quilts, quilting, quilted, quilter** and so on**.**

- The asterisk is also useful for searching variants spellings. For example, **alumin*m** will find matches for both the British **aluminium** and the American **aluminum.**

COPYRIGHT ON THE INTERNET

The Internet is the sort of place where it is extraordinarily easy to copy things, although it must not be forgotten that ease of copying did not start with the Internet. If something is physically easy to copy it does not mean that it is legal to copy it, or morally acceptable to copy it. Absence of a copyright notice does not mean it is okay to copy it.

When using information taken from the Internet, always reference the Web site, the title of the information and the author. It is also important to reference the date of the information on the Internet.
