Consider a single server queuing system where customers arrive at a service center according to the following schedule:

Customer	Arrival Time (minutes)	Service time
1	0	5
2	2	4
3	5	3
4	7	6
5	10	2

Assuming the system operates under FIFO (First In, First Out) discipline and there are no other customers present initially:

1. Find the total number of delays
2. Determine the time each customer spends in the system (including service time and waiting time).
3. Calculate the total time each customer spends waiting in the queue.
4. Determine the total number of customers in the queue at each time point.
5. Calculate the expected average number of customers in the queue over the duration on the simulation (for n delays)
